

That setup makes total sense for an AI-driven workflow. Organizing your Google Drive into distinct .pdf, .md, .jsonl, and skills.md directories creates a predictable, structured layout that makes it much easier to point your agents exactly where they need to look.

Since you are mapping out this architecture, here is a breakdown of how to structure your files so you can run tools like grep over them or point your agents directly at specific contextual blocks.

Optimal File Layout for Agents

- **Markdown (.md):** Best for text context, standard operating procedures (SOPs), and general agent instructions. It provides a clean, text-only layout without heavy code overhead.
- **JSON Lines (.jsonl):** Perfect for structured logs, database exports, and multi-turn conversation training histories. Agents can read this line-by-line efficiently.
- **PDF (.pdf):** Great for static document backups, formal invoices, and layout-dependent records.
- **skills.md:** Serves as your remote tool routing file. By pointing an agent platform at this file, your AI can automatically pick and load specialized remote tools into its context as needed.

How "Grep" Fits Your Workflow

Because you are working in Google Drive, standard terminal tools cannot scan your files directly without an ingestion step. To make files searchable for commands like grep:

1. **Sync Files:** Use a tool (like Google Drive for Desktop or an API sync script) to clone your directory structure to a local workspace or the machine hosting your agents.
2. **Execute Commands:** Once local, you can use the syntax `grep -r "your-search-term" ./your-folder/` to search inside all your text-based .md and .jsonl files at once.

Are you looking for an **automated script** to export your Google Docs into these exact formats, or do you want to explore how to connect your new folder structure to a specific **agent framework**?
