

Canonical build sequence and priorities

In priority two and priority three some very important guidelines that need to be formalized and transferred into machine executable skill assets will also include obi One protocol, utilizing reasoning Bank and making sure that documentation data memory skill building etc can all access the same universal tools I.e the wiki notebook graphify obsidian vault

Priority 3 part of the clean file management layers local workspace infrastructure and local markdown vaults are also going to require and utilize a completed llm wiki schema working open wiki a functional graphify and obsidian skills layer and notebook lm-py. the first repo that will be bootstrapped will be the one defining the files management protocols and how to properly structure a GitHub repo and it's literally going to refer to the obsidian repo and skill and how to use and manage notebook and graphify

In priority 4 another piece of this file management data collection and information access that needs to be verified in this loop is the deployment layers ie mem0 & Omni route. This would actually be the ideal time to also create the emulated environment for model deployment we can literally get the ob1 protocols the reasoning Bank Omni route how all of these access the llm wiki graphify obsidian and notebook we can map out the parameters for the Aesop XI protocols all the model weights functioning memory size, etc but honestly I think the only thing we need to know is that the pipeline works so that in the next priority priority five it would be a combination of making sure the kotlin Java APK layer can actually be deployed and survive while also coding out the rest of the Aesop.parameters rules failbacks etc fine tuning m e m 0 reasoning Bank and how ob1 truly dictates while also making sure open route is as advertised and doesn't need tweaking

you can't have a fully liberated on device agentic assistant without the UI or the memory layers and tool calling schema / supporting harness.

So that after priority 5 priority 6 would incorporate perfecting every aspect of the horizons UI and the Aesop XI so that novus a gentai is a fully documented truth and canonical resource/repo

In section 2 item one you have open Brain protocol back end I am two reasoning bank for The ledger and should also have an item three for the mem zero layer and part of all of these deeper integrations but also involve their ability to utilize those established knowledge layers in all the aspects that you listed

After all that is verified and working the resulting environment will help define building out the rest of th ui

Now that we have the first wave of priorities ironed out I'd like to see this deeper library of build matrixes and run time execution schema etc that you have everything but fully defined or properly coded can be edited right now and closing out this session with that would be perfect

so besides the global information layer and storage matrix deep integration skill construction schemas and directions protocol and that execution repo script

You can edit and reshare the corrected pr updated.. you had the isolated repository bootstrap checklist the multi repo daisy chain sink can be updated as can all well not all but I'm sure but at least one two three four yeah I mean pretty much all of it can be automated.

Repository catalog and individual Scopes can be upgraded and listed capability pipeline can be upgraded and listed the data curation layer structural priority path the master blueprint documentation documentation templates step by step task workflow engine actually and that was predocumented corrections and record realignment

Some other notable documentation that you made that would be nice to have edited and pushed as complete would be the skill construction and data set loading protocol you have here number three the master repository and data directory blueprint and number two and number one you have is the master build guide canonical architecture and mid note executions template and then finally I see the the house the data flow and tool control execution and finally the master repository and data directory blueprint and the data flow and tool control execution pardon the repeat

You can include the corrected json-rpc Trace schema for manual audit. Revised ground truth priority build order the GitHub CI CD layer and multiple repose segregation manifesto capability pipeline skill building protocol closed loop verification protocol data curation layer configuration local file systems verifiers that's an important one too to get right and it'd be nice if you could do the master repository and data directory blueprint in a format that I can actually edit so I can add to it or subtract or move it around as needed

I'm not sure if the system integrity auditor needs editing or if the root execution guide but I really liked the horizon stack map the Aesop XI stack and the system data flow blueprint but they were both missing several items a and the readme's the three important readings that you provided that I asked for those at the top of the session those came out pretty good just missing a couple things I'm not sure if it's possible to add to those or give me the revisions and then one last thing on that exporting the conversation via bookmark when you say it cleans up the text what do you mean by that do you mean that it erases part of the conversation and streamlines it summarizes it or what does it just get grabbed or does it actually get cloned
