

—**Droid DeX** (often officially listed as **Android-Dex** or bundled via installers like DroidDesk) is an excellent choice for the **Samsung Galaxy Tab S9 FE**. It handles the automated installation scripts and leverages a built-in XFCE4 desktop with much smoother performance. [1, 2, 3]

Step 1: Disable Child Process Restrictions

This is the most critical step for compilation tasks like building *Trusted Firmware-A*. Without this, Android will automatically shut down your Linux terminal if it uses too much background processing power. [4]

1. Go back to your main **Settings** menu and tap the new **Developer Options** row at the very bottom.
2. Scroll down until you find the "**Disable child process restrictions**" toggle (sometimes labeled under App/Process management limits).
3. Turn this toggle **ON**.
4. While in this menu, turn **USB Debugging** to **ON** as well (this helps the display driver link smoothly). [1, 4, 5, 6]

Step 2: Disable Battery Optimization

Ensure Android does not put your Droid DeX environment to sleep while you are coding.

1. Open **Settings > Apps** and find your **Droid DeX / DroidDesk** app.
2. Tap **Battery** and switch it from *Optimized* to **Unrestricted**. [4]

Step 3: Launching and Installing VS Code

Now you are ready to boot your Linux environment.

1. Open the Droid DeX app on your tablet.
2. Tap **Setup Desktop Essentials** and select **XFCE4** to initiate the clean desktop installation.
3. Once complete, tap **Launch Desktop**. Your screen will load into the XFCE4 graphical workspace.
4. Pull up the Linux terminal browser or the app manager inside the desktop environment and pull down the **Linux ARM64 (.deb)** archive directly from the [Official Visual Studio Code Download Page](#).
5. Install it directly through your terminal using:

```
sudo dpkg -i <downloaded-vscode-package>.deb
```

[2, 4]

If you'd like, let me know:

- - Have you successfully downloaded the **Droid DeX installation asset (.apk)** to your tablet yet?
 - Do you want the baseline command line setup to verify your **Arm toolchain and GCC compiler** once you boot inside the system? [2]
1. **Do I need a user script to pass off as a PC desktop for downloading web apps? Is it even possible that get web apps in Chrome using this route?**
 2. **You didn't tell me this thing requires a PC what good is it to me then? Does this support termux?**
