

You are looking at the components of a **Personal Agentic Operating Stack** (or a **Cognitive Architecture Stack**).

When you bundle Open Brain (OB1), mem0, LLM Wikis, and reasoning banks together, you aren't just configuring "settings"—you are building a **Cognitive Infrastructure**.

Here is how those specific pieces categorize under that umbrella:

1. The Core Infrastructure (The Backend & Protocol)

- **Nate B. Jones's Open Brain (OB1) / Obi-Wan:** This is your **Unified Memory Protocol & Persistence Layer**. It's the structural database design (separating raw data from embeddings in SQL via MCP) that ensures *any* AI you plug into it shares the exact same memory of you.
- **mem0:** This acts as the **Dynamic Memory Management Layer**. While Open Brain handles the structural storage sink, tools like mem0 manage the continuous extraction, updating, and pruning of user preferences and facts on the fly.

2. The Context & Knowledge Layers (The Brain's Workspace)

- **LLM Wiki / Wiki MD Architecture:** This is your **Conceptual Knowledge Graph**. It's the human-and-AI-readable markdown structure (using internal linking) that replaces bloated RAG with clean, traversable topical trees.
- **Reasoning Bank:** This is your **Cognitive Execution History / Epistemic Ledger**. Unlike raw data, a reasoning bank stores *how* problems were solved, successful multi-step logic paths, agent trajectories, and decision-making templates so the agent doesn't have to reinvent the wheel next time.

Summary

If someone asks what you are building, you tell them you are spinning up a **Local Agentic Cognitive Architecture** backed by an **Open Memory Protocol (OB1)** and a **Structured Markdown/JSONL Knowledge Pipeline**.
