Immutable External Vendor Documentation & Architecture Registries

W5+H Subsystem Identity

- **WHO:** Managed by the Ingestion Pipeline; queried strictly via OB1 and MCP by Large Query Models.
- **WHAT:** Millions of tokens of static vendor documentation (Qualcomm QAIRT SDK, Android OS, Unsloth, Llama Server).
- **WHEN:** Queried on-demand when compiling native C++ daemons, configuring NPU quantization parameters, or debugging Android OS service permissions.
- **WHERE:** [nova-xorpus/vendor-corpora/](#) (Federated Subsystem Root).
- **WHY:** Isolates heavy external documentation so it does not drown internal conceptual wiki graphs or pollute active prompt contexts.
- **HOW:** Read-only directory partition indexed by localized [manifest.jsonl](#) files and accessed via targeted MCP tool calls.

Internal Directory Topology

└─ gguf-export/	# Export guidelines for Q4_K_M and GGUF architectures

Beginner-Proof Implementation Rules

1. **Strictly Read-Only:** Never edit files in this tree. They are immutable vendor references.
2. **Selective MCP Ingestion:** Never dump an entire vendor directory into an agent prompt. Agents query specific structs (e.g. `ASharedMemory_create`) via MCP to pull only the matching 15 lines.
