

Yes, the task-observer includes an interactive human-in-the-loop gating framework designed exactly for this. By default, it **never applies updates automatically**. It stages them silently in your workspace directory, forcing Claude Code to display a complete breakdown for your manual review and approval before anything propagates into your system. [1, 2, 3, 4]

The workflow maps out directly into your TUI terminal through two core mechanics:

1. The Dynamic Task Gating Interface

Whenever you boot a new task session—and at least 7 days have passed with open logs—the task-observer intercepts Claude's initialization. It prints a clean terminal interactive grid: [2, 5]

-
- It surfaces every accumulated observation grouped cleanly by skill.
- It forces Claude to pause execution entirely and **wait for your explicit confirmation**.
- You can accept, reject, or manually adjust individual behaviors before the underlying code changes ever touch your repo. [2]
-

2. The Local Staging Architecture

If you don't want to wait for the automatic weekly review cycle to trigger, you can browse and manage the raw staged changes natively at any time inside your project tree: [1, 4, 5]

```
# View pending updates the observer has compiled from your corrections  
cat skill-updates/proposed-changes.md
```

```
# View the raw chronological history tracking your hot/cold memory states  
cat skill-observations/observation-log.md
```

Nothing modifies your active folders or your personal forks behind your back. The task-observer logs the raw behavioral signals completely passively, then holds the resulting skill modifications in the skill-updates/ staging zone as a literal pull-request review layout waiting on your terminal command. [1, 3, 4]

Would you like to force-trigger an **immediate staging review** in your TUI right now to see how the formatting handles your layers, or do you want to configure a **custom review interval** (like every 3 days instead of 7)? [5]
