

Yeah I need to merge that to main and I also need that skill or tool right up I guess it's going to be both or or just one what's the best way to utilize this I also want to get this JSONL file markers or jsonl identifiers or whatever you call that I want to get that all mapped out and documented so that I can implement that throughout my database

Another question about what we were talking about so I'm using open weights models and I'm typically going to have the same ones for the same tasks right does that mean that that model actually retains information I mean doesn't it just wipe clean after every session just like any other one does and if not then how do I keep it from getting bloated and ended up getting dumber I mean I know that's the whole point that I'm utilizing the dual agent setup I'm going to have one small like a point eight 0.8 B qwen 3.5 gguf q4_0 and qwen 3.5 9B gguf Q4 _0 for the query and executive models and utilize the m e m0 protocol for that and I reckon the whole point of that is the they stay task oriented and don't really have to learn anything about me really or get context bloat

Now as far as my home node goes I haven't quite iron that out yet I'm thinking I'm definitely going to utilize the agent platform in gcp used to be called the vertex AI garden or something now I it's like that for Enterprise app building I have like \$1,000 credits for those it's like you can build query apps basically it's basically exactly what I'm doing I can have a model that's it searches a database to answer questions right so it could work really good as IT auditor compiler extractor I mean it could it fits right in there it's across agent auditor and script collector or a script writer agent and there's a couple things I wanted to try there's they have like big documented papers I think I have some of them they're even in the some of this material that you had to go over about how to build your own agent on device agent I think it's like using Nano so there's the Nano agents there's also wanted to experiment between those and turboquant and smol agents for my npu manager my shell or terminal assistant application as well as the help desk operator manual agent and the news updates and breaking or trending repository models trends etc the agent that's going to help with all that stuff web search and whatnot I'm just trying to figure out a good way to break this workflow up and how if I designate certain models to one thing do I have to cycle them out or is the training process kind of a new clean sweep kind of gives it up like an enema and a tune-up at the same time

Also I'm not sure if you know much about how I plan on utilizing my own device agent as far as inference with frontier models and web hooks and interaction with other clis and whatnot but it's actually going to be primarily used as a go-between like a concierge basically like it'll take you know one instance like right now I'm in cloud code well once my on device agent I would just have to push the button where it pops up on the screen talking to the microphone give it my prompt or whatever my question is and instead of it being a 1,000 line paragraph with no. And a complete run on sentence of typos it would construct a clean markdown metaprompt that I could look at and approve of and then it would send and then I would once you typed your output it would already have the TTS dialed in with the screen vision so it would automatically start

reading your output to me real time with that vad implemented so I could interject if I wanted to and then after the reply I would either give it further directions as far as acting upon what the frontier model just said you know maybe there's a website that it needs to look up or document that it needs to upload or an action that it needs to perform so I'm wondering if I split that up between my big model and little model or if that's just kind of depending on the complexity of the task like right now I'm speaking you know sometimes I only say a paragraph sometimes in three pages in one prompt so if it was like a two line or one one paragraph prop maybe this fault model would automatically pick that up I don't know or does this all model always be the one that delivers or does the larger model need to be the one that that files into metaprompt and runs inference with frontier models because basically what's going to happen is this script training is going to be implementing every action from all three basically whatever frontier model or CLI for API tool that I'm utilizing I'm going to be interacting with it with my own device agents and then when I'm at home I'm basically going to have like a bottle of experts or a mixture of agents I guess I don't know which one would best serve that description to get this all documented so that it can go along with that architecture document for the grill session along with the skills or tools and that jsonl workflow that you were using and describing and that we could implement into all my database I need to get all of that documented right now I don't know if that's a artifact that I can see on my end or an entry into the repo or both I would prefer both maybe have a grill session prep file in the repo and we can get tuned up and then an artifact or three describing the things that I just went over
