

To force-trigger an **immediate staging review** right inside your Claude Code TUI session, drop this initialization block straight into your active terminal prompt:

"Execute the task-observer initialization routing now. Disregard the 7-day interval check. Aggregate all active history from skill-observations/observation-log.md and force-compile a staging evaluation grid comparing our mem0 logs and terrestrial-brain corpus configurations."

What Happens Next in Your TUI

1. Claude will bypass the default weekly pause condition and immediately call the task-observer scripts inside your local `.claude/skills/task-observer` fork.
2. It will parse the raw interactions, extracting exactly where it failed or succeeded across your three personal layers.
3. The TUI will freeze normal code operations and render an **interactive text layout grid** displaying:
 - **Staged Behavioral Optimizations:** The exact syntax and prompt-weight modifications it wants to add to your rules.
 - **Memory Sync Improvements:** Adjustments to ensure mem0 commands aren't cross-contaminating your cold Obsidian knowledge base.
4. It will display a strict confirmation prompt asking you to explicitly type yes, no, or provide manual line modifications before saving the updates down into your `skill-updates/proposed-changes.md` file.

Run that prompt block inside your current shell to instantly inspect the staging dashboard state on your hardware.
